## INTRODUCTION

Between 1968 and 1972 over 10,000 birdwatchers participated in fieldwork for the "Atlas of Breeding Birds in Britain and Ireland". This major ornithological survey was organised by the British Trust for Ornithology and the Irish Wildbird Conservancy and all records were collected and mapped using the 10km squares of the Ordnance Survey National Grid. This size of mapping unit proved adequate at the national level but somewhat crude when examining the distribution of birds at the county level.

Inspired by the success of the national project the decision was taken to repeat the survey of the old county of Huntingdonshire with Peterborough during the years 1979-1983. This time, however, the mapping unit chosen was the 2km square formed by the even-numbered lines of the O.S. National Grid, otherwise known as the "tetrad". Including those that overlap the county boundary, Huntingdonshire has 385 tetrads.

The categories used by observers when determining the status of a potential breeding record for the Huntingdonshire survey were those described and used in "The Atlas of Breeding Birds in Britain and Ireland". There are three main categories of breeding which can be summarised as follows:-

### Possible breeding.

Bird recorded in breeding season in possible nesting habitat.

### Probable breeding

Singing male.

Bird apparently holding territory.

Display or agitated behaviour.

Visiting probable nest-site.

Nest building.

### Confirmed breeding.

Distraction Display.

Used nest found.

Recently fledged young.

Adult carrying faecal sac.

Adult with food for young

Adult entering/leaving likely nest site.

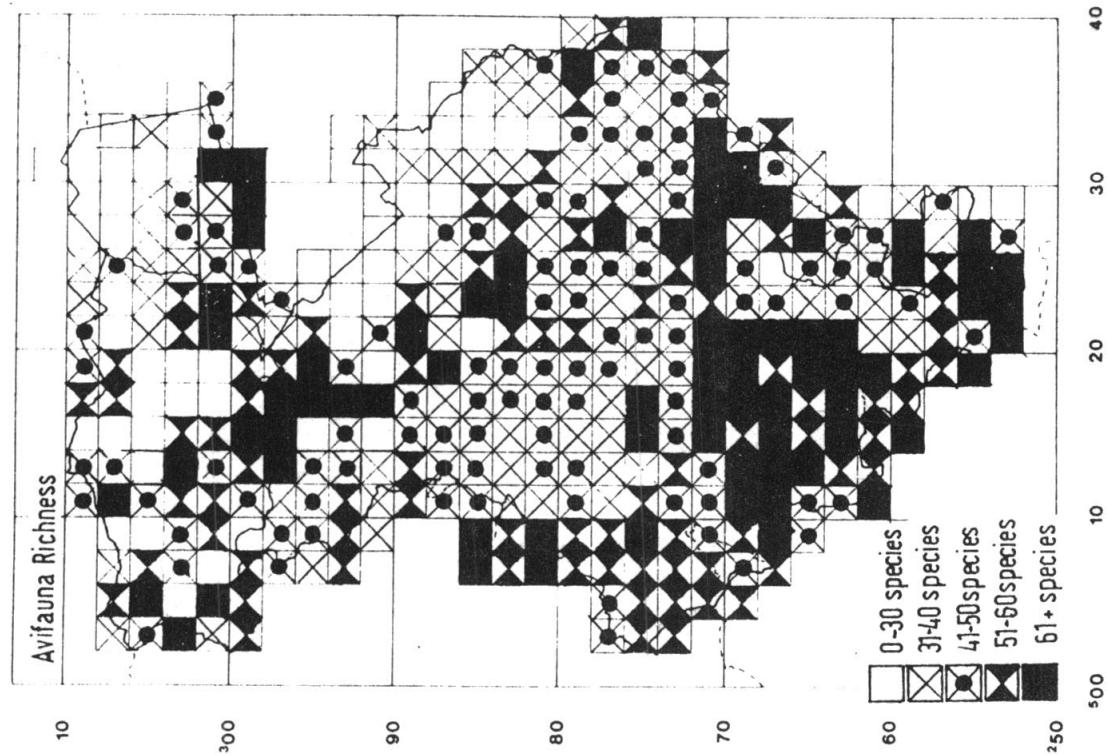

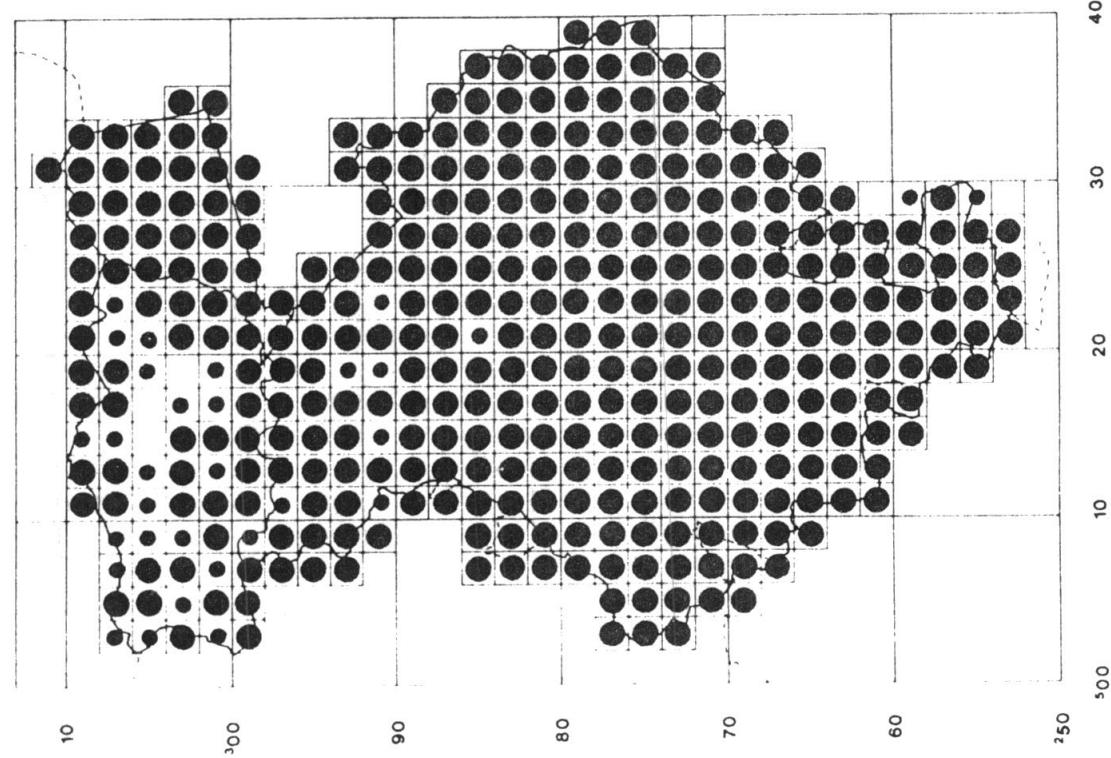

Nest and eggs/bird sitting tight.

Nest and young or downy young.

Records were collected by observers on recording cards which were submitted to the organiser at the end of each season. Recording cards consisted of a full species list with columns to enable the observer to enter the category of breeding recorded. The data from these cards were transferred onto master cards from which the maps were drawn. New cards were supplied annually along with details of the methods to be used and an update of progress.

The majority of the recording area was well covered, but records for some tetrads in the north of the county were not submitted hence there are no records for tetrads m, s, and w in square TF10, other tetrads in this 10km square and TF00 were poorly covered.

COVERAGE 1979-1983

## THE OLD COUNTY OF HUNTINGDONSHIRE

Huntingdonshire with the Soke of Peterborough constituted the second smallest county in England until 1974 when the reorganisation of county boundaries saw the area absorbed into Cambridgeshire. There are two main areas of development, Peterborough in the Nene Valley in the north and Huntingdon with St Ives and St Neots in the Ouse Valley in the south.

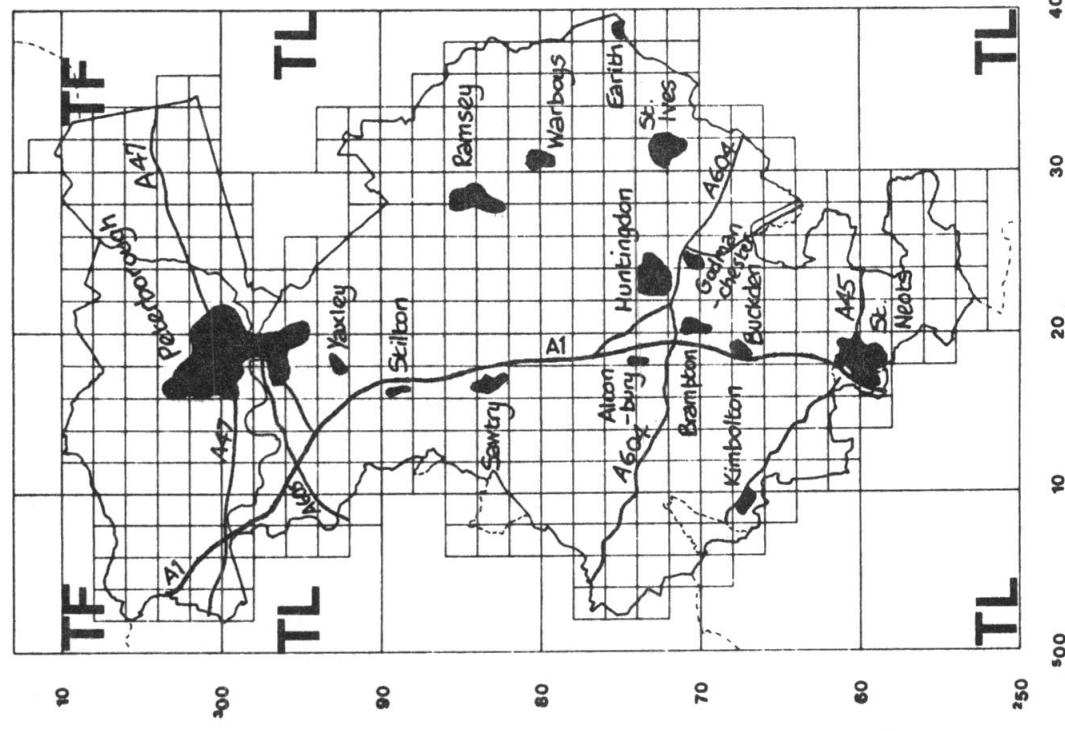

The majority of the County is situated on Oxford Clay, although there is a band of Lower Greensand in the very south. There is little variation in altitude across the area, the highest point being 250 feet (75m) above sea level and the lowest, in the Fens, several feet below sea level.

The rivers Great Ouse and Nene both cross the County from west to east. The Ouse carries water from Buckinghamshire and Bedfordshire and the Nene from neighbouring Northamptonshire. The northern border of the old County runs along the course of the river Welland for a short distance. There are large deposits of sand and gravel along all three of these river valleys, varying amounts of which have been extracted, resulting in a series of flooded gravel pits in each. In the Ouse valley a series of water-filled pits exists from Little Paxton past Buckden, Brampton and Godmanchester to St Ives and Earith in the extreme east of the County. In the Nene valley, water-filled pits exist between Wansford and Peterborough, while to the north, in the Welland valley, there are flooded diggings at Maxey.

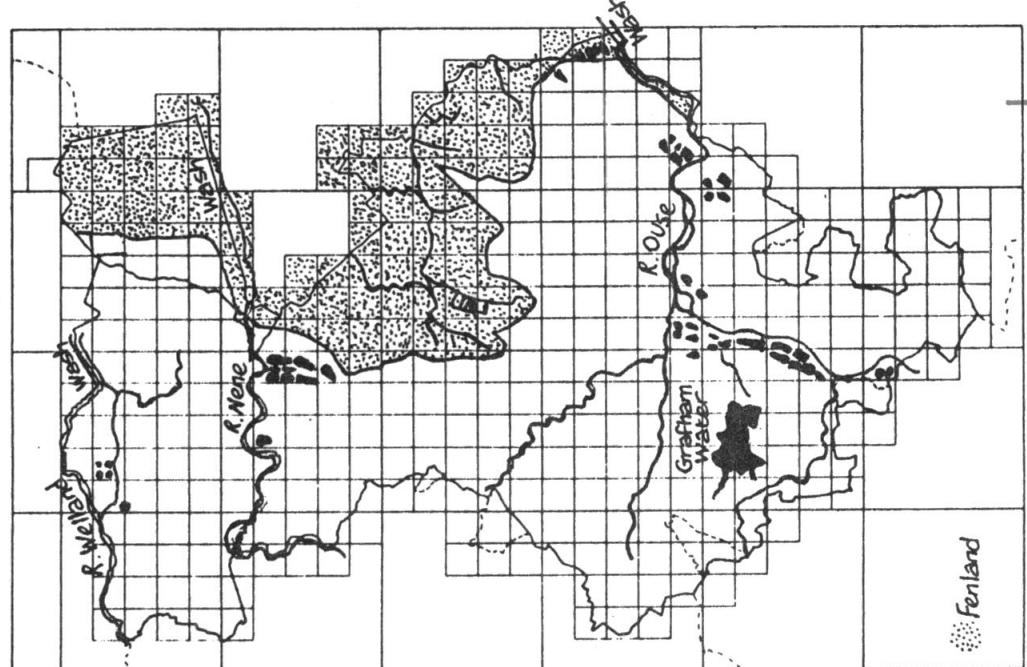

The old County has very little woodland, most of which is located in the north-west and west on the heavier clay soils. The fen carr which once covered much of the lower areas of the old County has long since been destroyed, although there are important remnants at Holme Fen and Woodwalton Fen.

In the south of the County is Grafham Water, one of the largest man-made reservoirs in Europe. Although now used extensively for water-based recreational pursuits, the area is of major importance for waterbirds and will undoubtedly continue to be so.

## RESULTS

Over the five years that the Survey was carried out, all but three tetrads, out of 385, were covered. A grand total of 18,074 records were collected relating to 108 species. A number of confidential records were submitted and these have been omitted from the printed maps and amount to 65 records.

The avifauna richness map reflects many trends which are apparent in many individual species maps. Areas which were particularly rich in species were the river valleys including the gravel pits and the areas with the most extensive woodland, the latter situated in the west and north west of the County.

The Fenland areas in the north east of our area are notable for the distinct lack of species and numbers of individuals. The escarpment at the edge of the Fens can be clearly seen crossing TL 38, TL 28 and TL 29. The distribution maps of species such as blue tit and robin show how the common woodland and garden birds are scarce in Fenland, whereas reed warbler is almost restricted to the Fens and river valleys. The open, often treeless, habitat of the Fenland area is inhospitable to many species.

One species that has changed its distribution within our area since the survey was carried out is the magpie. The map for this species shows the period when it was most restricted in range. It will be interesting to see future maps for this and all other birds located during this survey.

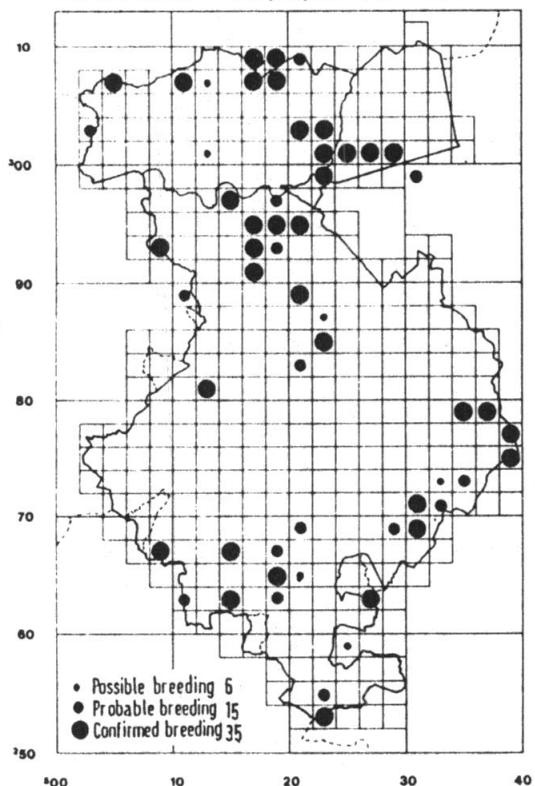

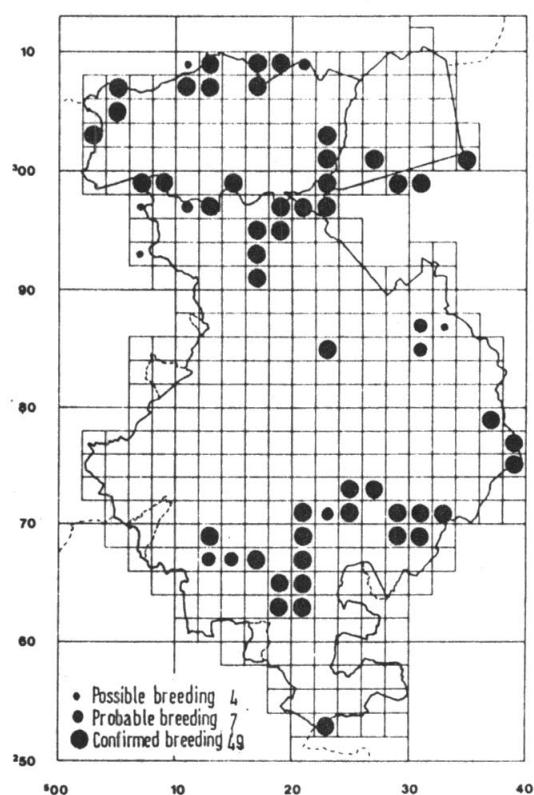

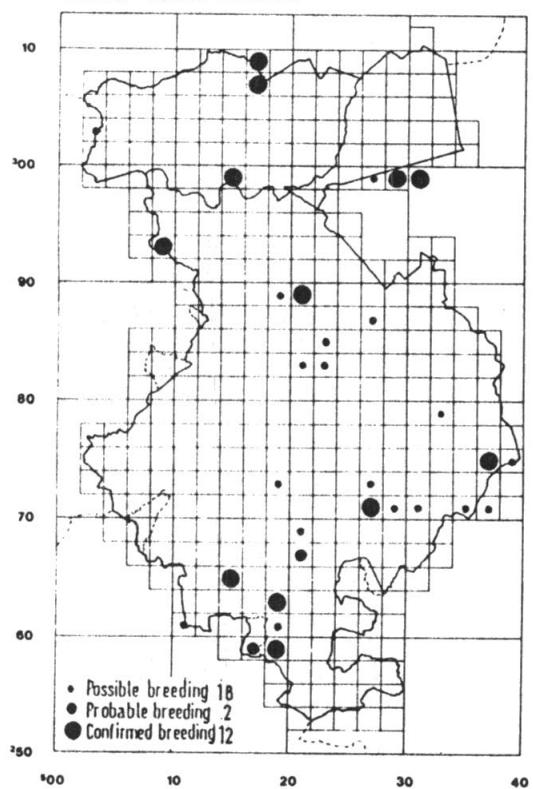

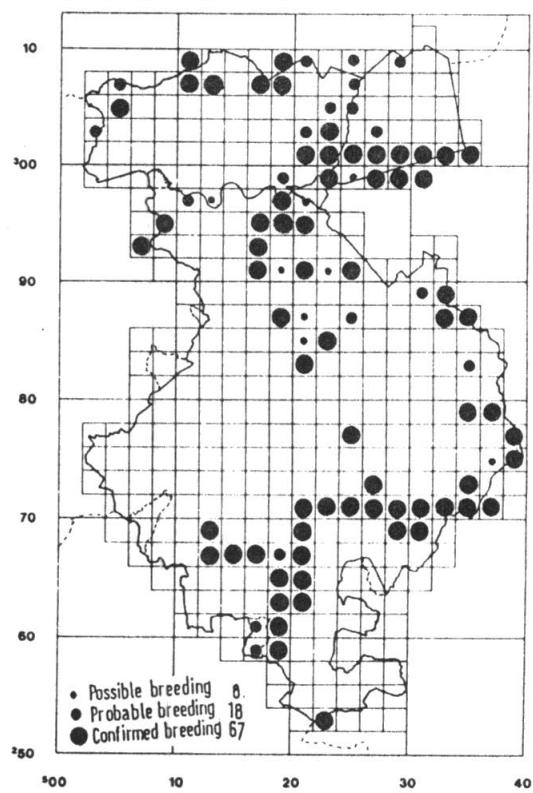

Many of the wildfowl species have only been recorded breeding in the old County for a short period of time, colonisation coinciding with the advent of deep gravel pits and Grafham Water. Shelduck was first recorded breeding in 1966, teal in 1951, gadwall probably in 1952 and garganey in 1953. Some waders have benefited due to gravel pits to the extent that the County has become important for ringed plover and little ringed plover. Other species such as redshank, snipe and lapwing are probably much less common now than they were previously due to land drainage. The draining of the Fens in earlier years must have had a major impact on bird distribution within the area.

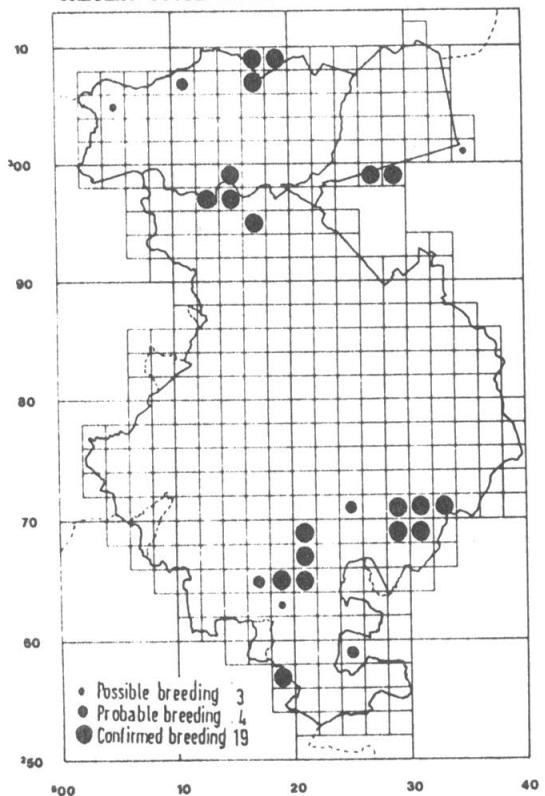

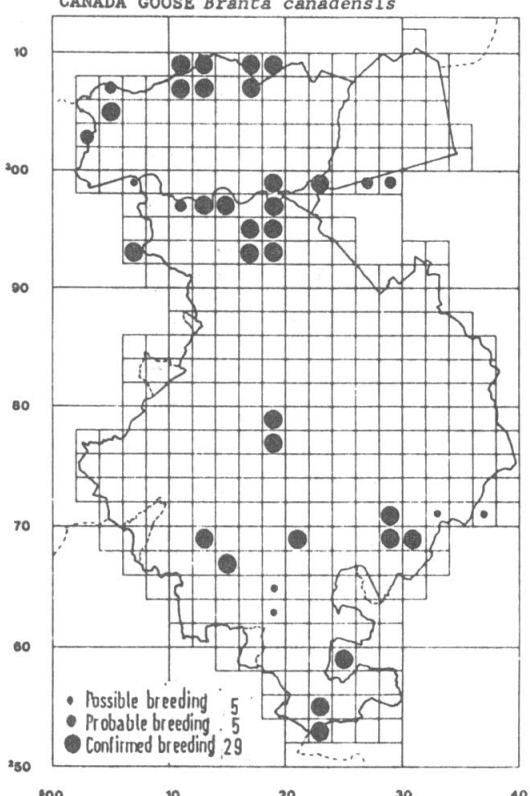

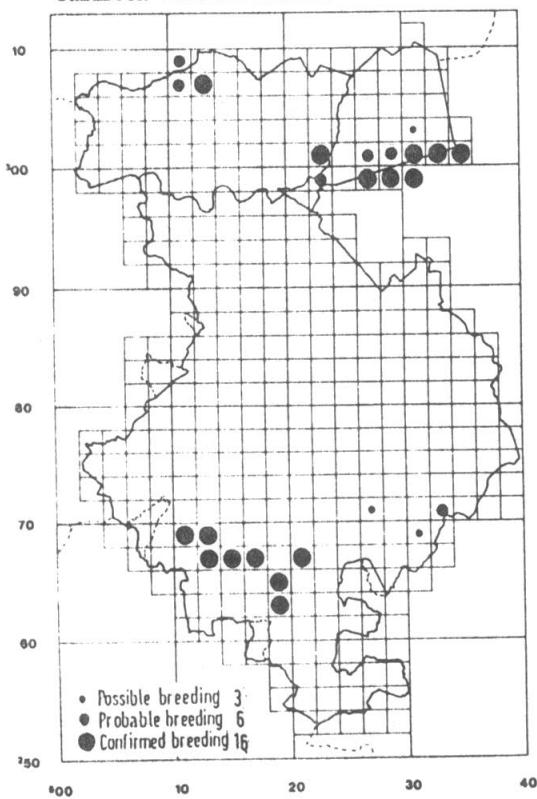

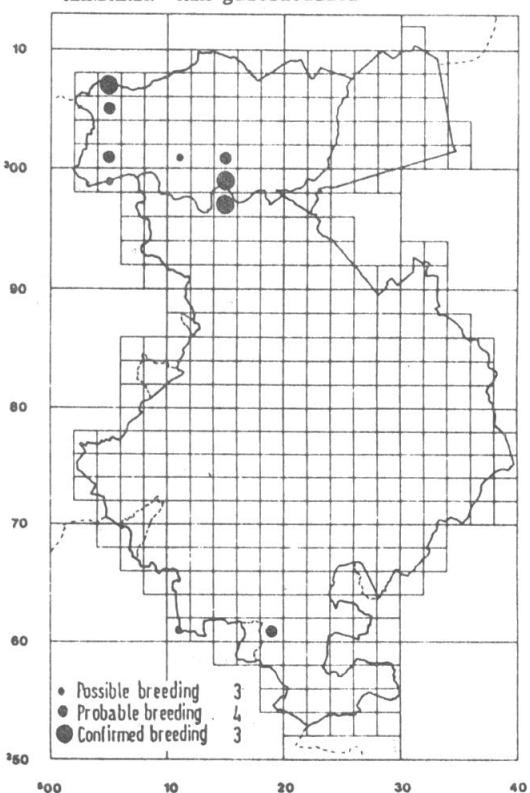

The winter before the Survey started was very hard and reduced the numbers of many resident species drastically, kingfisher, goldcrest and coal tit were particularly affected. During the Survey, winters were relatively mild and by the end of the fieldwork numbers had shown a considerable increase.

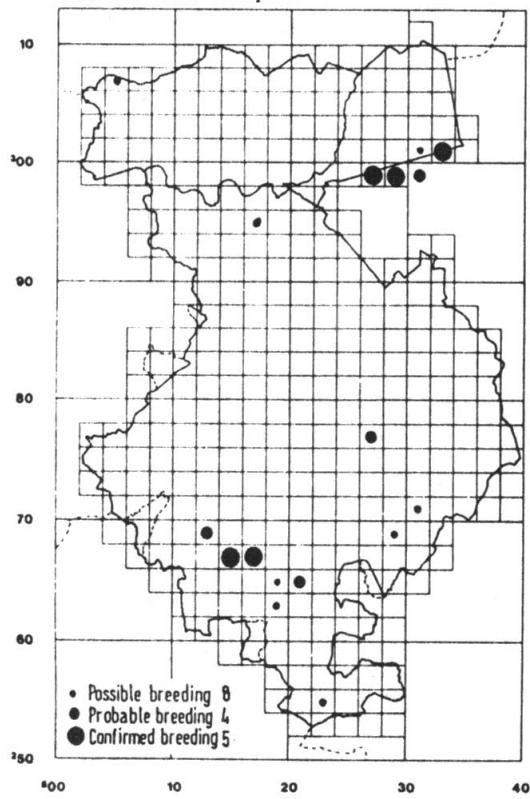

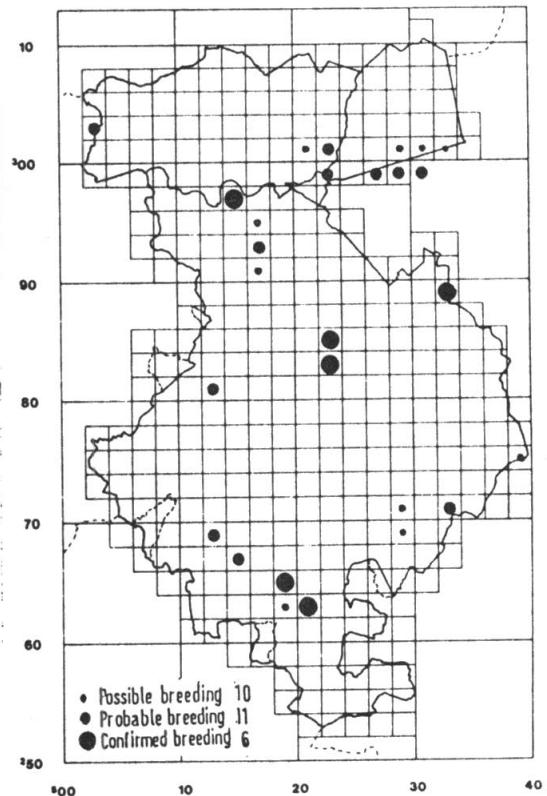

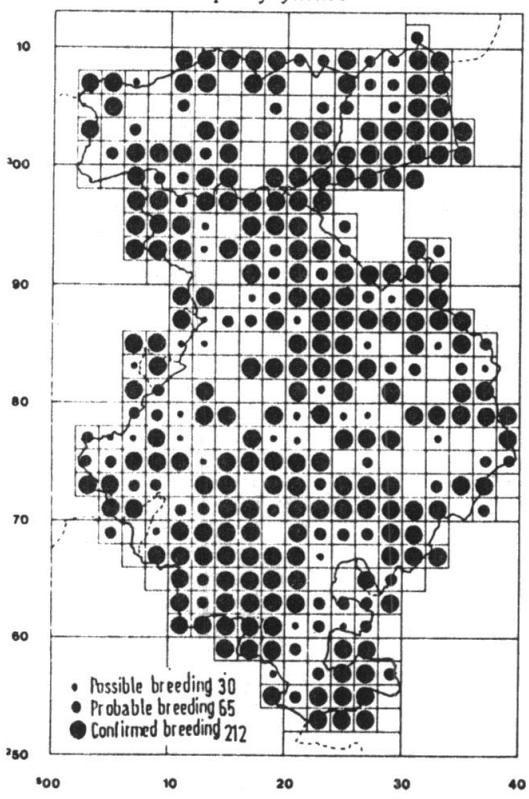

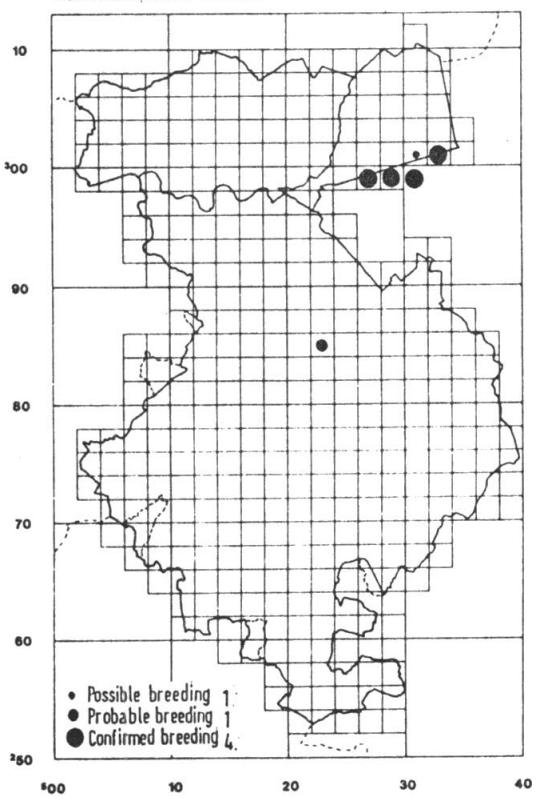

The aim of this survey was to provide a baseline showing the distribution of all species breeding within the Old County. The two previous avifaunas of the County, The Victoria County History and The Birds of Huntingdonshire by C.F.Tebbut, give us some indication of previous distribution. However, the rate of agricultural and other land-use change since their publication has become increasingly rapid and both are now outdated.

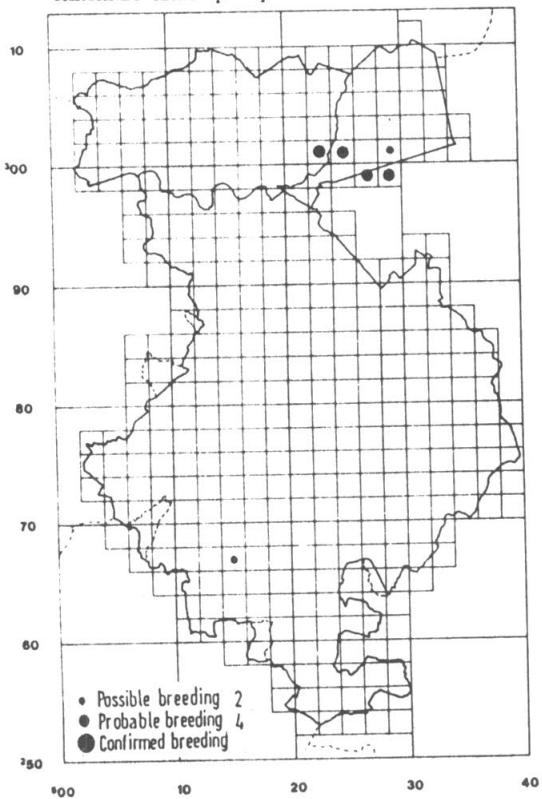

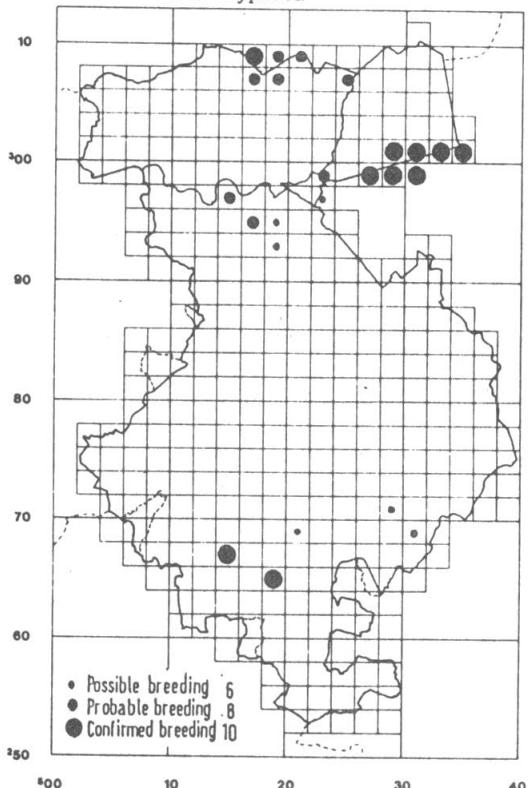

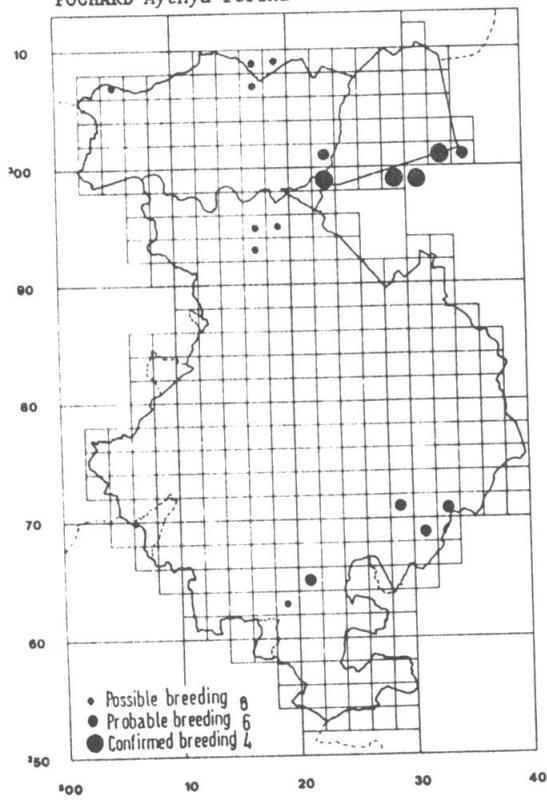

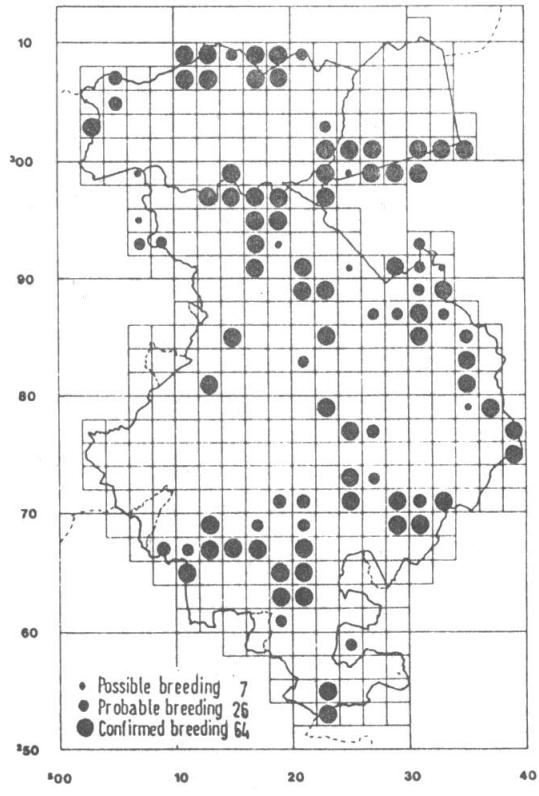

Summaries of bird records for the Old County of Huntingdonshire are published annually by the Huntingdon Flora and Fauna Society and the Cambridge Bird Club.

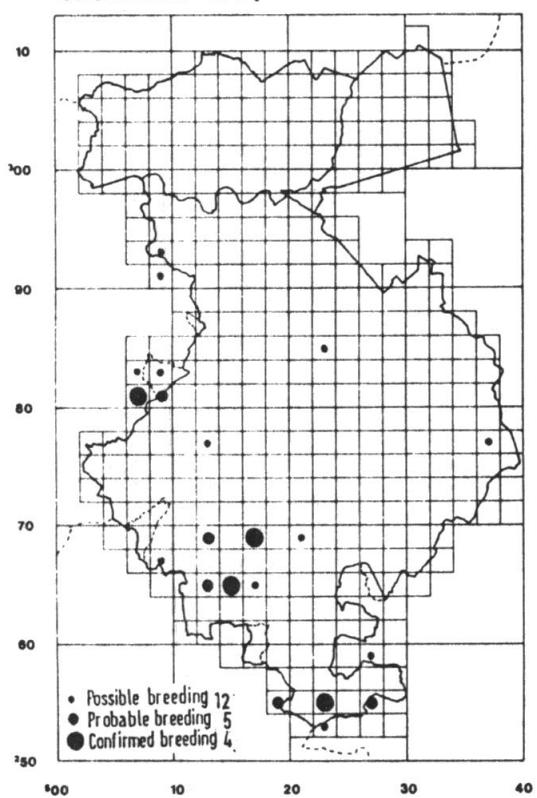

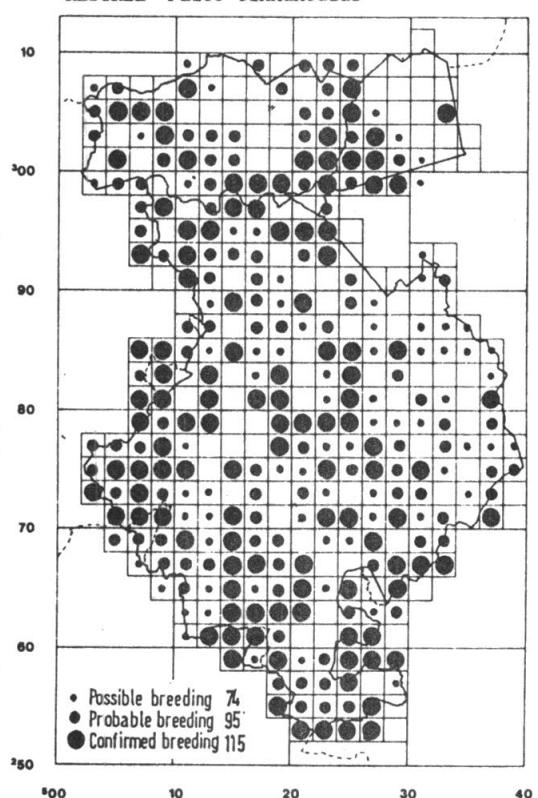

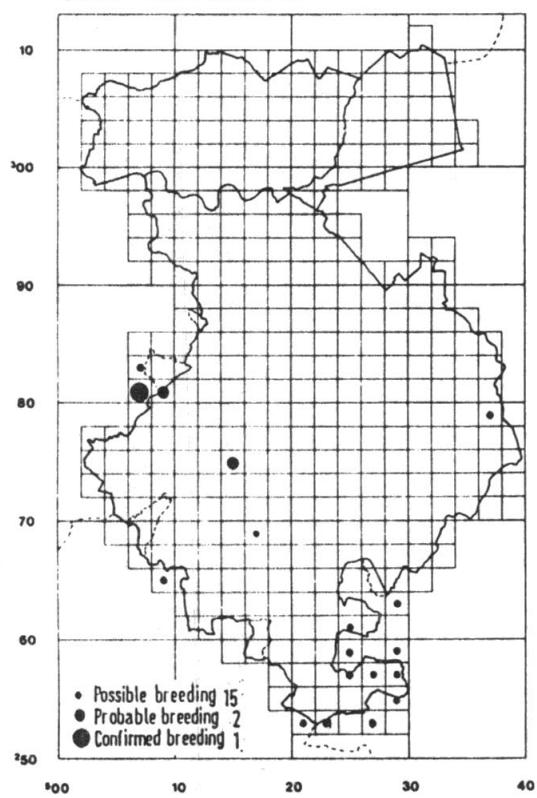

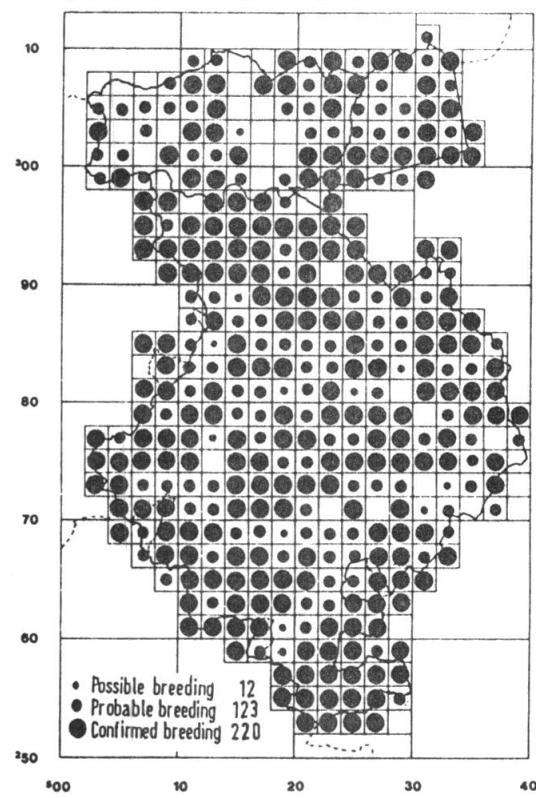

This publication owes much to all those observers who participated in the survey. Without their effort this publication would not have been possible.

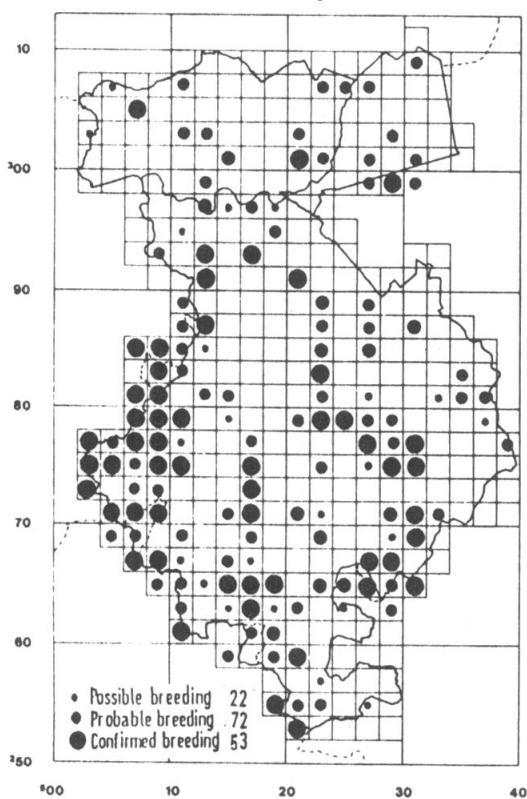

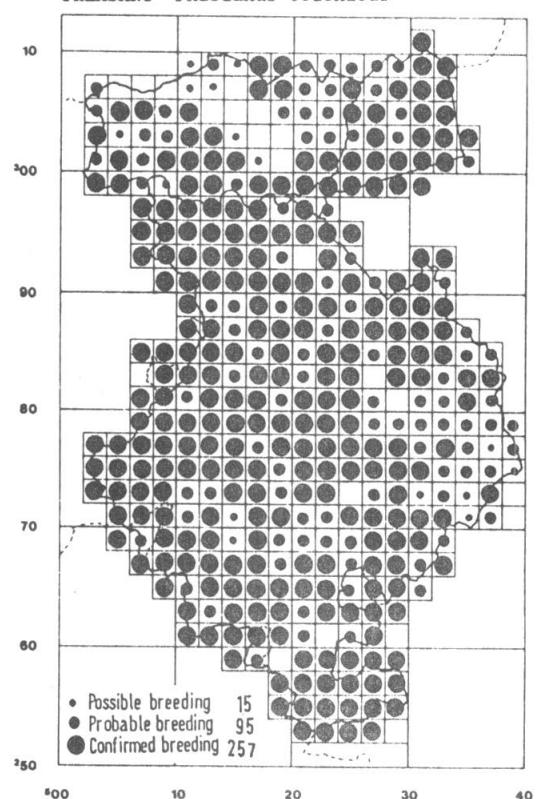

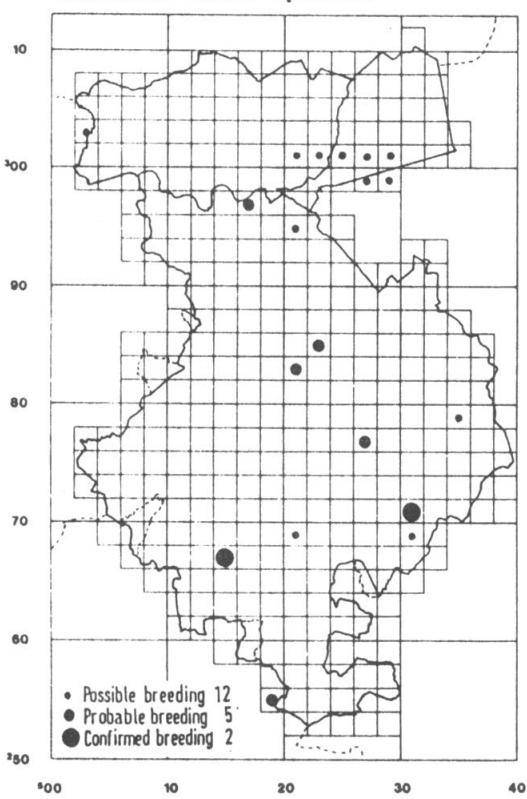

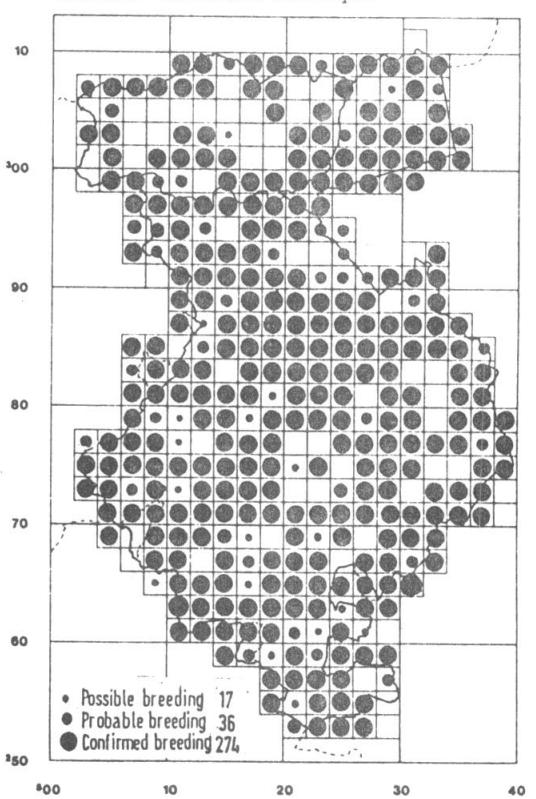

LITTLE GREBE *Tachybaptus ruficollis*GREAT CRESTED GREBE *Podiceps cristatus*HERON *Ardea cinerea*MUTE SWAN *Cygnus olor*

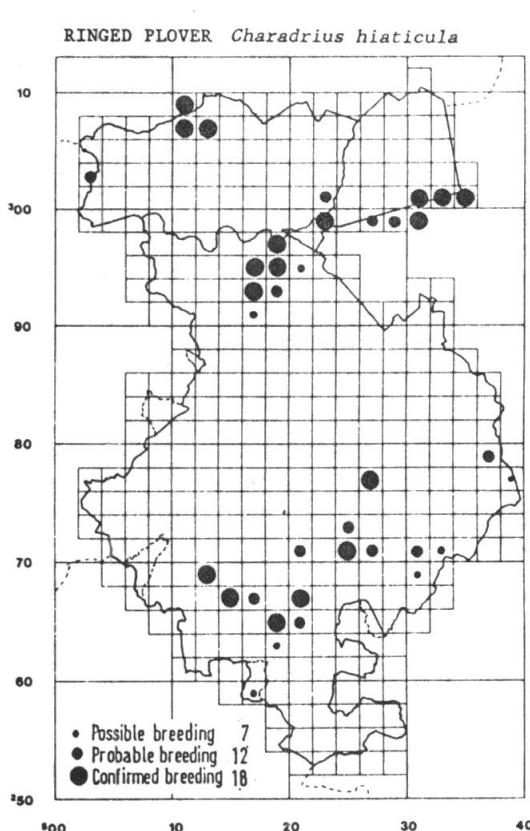

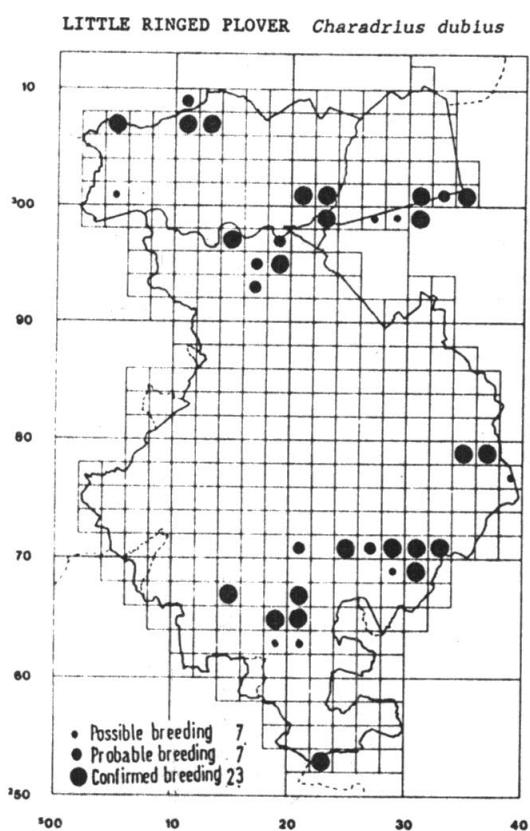

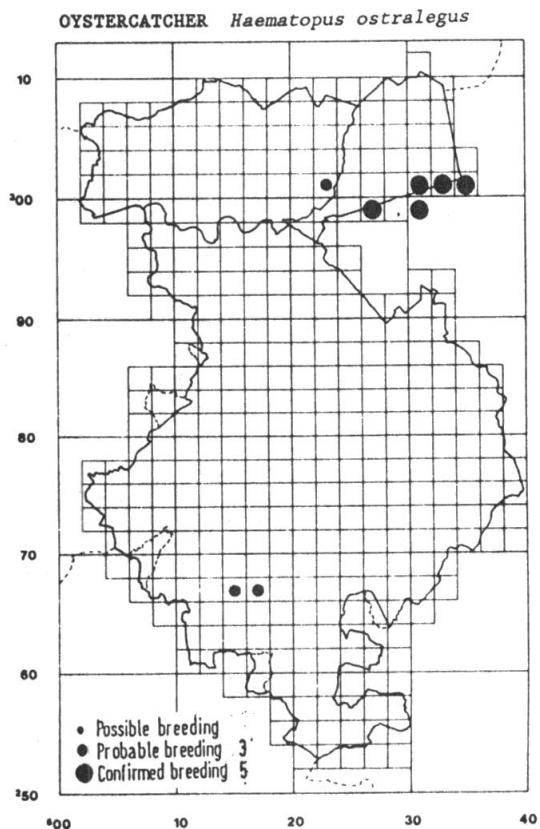

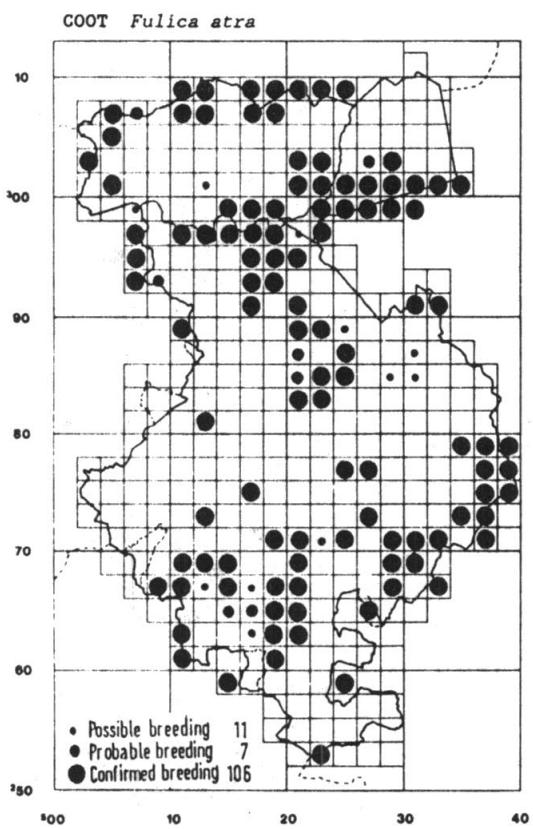

GREYLAG GOOSE *Anser anser*CANADA GOOSE *Branta canadensis*SHELDUCK *Tadorna tadorna*MANDARIN *Aix galericulata*
